1 string

1.1 kmp

next[j] 的值表示 P[0...j-1] 中最长后缀的长度等于相同字符序列的前缀。
j 为最远位置使得 mod[0..j-1] == mod[i - j+1 .. i]
next 的值就是每个 j nxt 往前
重要的是理解那个往前
例：ababa nxt 为：0 0 1 2 3
那么 nxt[nxt[5]] = nxt[3] = 2; 即 s[0..1] = s[2..3]

性质：Len-nxt[len-1] 就是从 0 开始最短的串能重复出整个串，比如 abcabcab 就只需要 abc 就能重复完

```
int len1,len2, nxt[10005];
char mod[10005], s[1000005];
void get_nxt(char mod[],int len){
  int i,j=0;
  nxt[0]=0;
  for(i=1;i<len;i++){
    while(j>0 && mod[j]!=mod[i]) j=nxt[j-1];
    if(mod[j]==mod[i]) j++;
    nxt[i]=j;
  }
}
int KMP(int len1,int len2,char s[],char mod[],int pos = 0)
{
  int i=pos,j=0,ret=0;
  while(i<len1){
    while(j && mod[j]!=s[i]) j=nxt[j-1];
    if(mod[j]==s[i++]){
      if((++j)==(len2)) ret++;
    }
  }
  return ret;
}
```

1.2 ekmp

q 是 B 串继续向后匹配的指针，p 是 A 串继续向后匹配的指针，也是曾经到达过的最远位置 +1
q 在每次计算后会减小 1，直观的讲就是 B 串向后错了一位

```
const int N=100010;

int len_s,len_t;
int nxt[N],extend[N];
char S[N],T[N];
void build_nxt()
{
  int k, q, p, a;
  nxt[0] = len_t;
```

```
10    for (k = 1, q = -1; k < len_t; k ++, q --) {
11      if (q < 0 || k + nxt[k - a] >= p) {
12        if (q < 0)q = 0, p = k;
13        while (p < len_t && T[p] == T[q]) {
14          p ++, q ++;
15        }
16        nxt[k] = q, a = k;
17      }
18      else {
19        nxt[k] = nxt[k - a];
20      }
21    }
22  }
23  void extend_KMP()
24  {
25    int k, q, p, a;
26    for (k = 0, q = -1; k < len_s; k ++, q --) {
27      if (q < 0 || k + nxt[k - a] >= p) {
28        if (q < 0)q = 0, p = k;
29        while (p < len_s && q < len_t && S[p] == T[q]) {
30          p ++, q ++;
31        }
32        extend[k] = q, a = k;
33      }
34      else {
35        extend[k] = nxt[k - a];
36      }
37    }
38  }
39  int main(){
40    fi;
41    scanf("%s",S);
42    scanf("%s",T);
43
44    len_t=strlen(T);
45    len_s=strlen(S);
46    build_nxt();
47    extend_KMP();
48
49    return 0;
50  }
```

1.3 manacher

最长回文子串模板
hdu3068，最长回文子串模板，Manacher 算法，时间复杂度 O(n)，相当快
str 是这样一个字符串（下标从 1 开始）：
举例：若原字符串为"abcd"，则 str 为"$#a#b#c#d#"，最后还有一个终止符。
n 为 str 的长度，若原字符串长度为 nn，则 n=2*nn+2。
rad[i] 表示回文的半径，即最大的 j 满足 str[i-j+1...i] = str[i+1...i+j]，
而 rad[i]-1 即为以 str[i] 为中心的回文子串在原串中的长度

```
#define M 20000050
char str1[M],str[2*M];//start from index 1
int rad[M],nn,n;
void Manacher(int *rad,char *str,int n)
{
    int i;
    int mx = 0;
    int id;
    for(i=1; i<n; i++)
    {
        if( mx > i )  rad[i] = rad[2*id-i]<mx-i?rad[2*id-i]:mx-i;
        else rad[i] = 1;
        for(; str[i+rad[i]] == str[i-rad[i]]; rad[i]++);
        if( rad[i] + i > mx )
        {
            mx = rad[i] + i;
            id = i;
        }
    }
}
struct PLD{
  int l,r;
  PLD(int x=0,int y = -1):l(x),r(y){}
}p[N];

void getlr(int n){
  fr(i,2,n){
    p[i].l = i-rad[i]+1;
    p[i].l = (p[i].l+1)/2-1;
    p[i].r = p[i].l+rad[i]-2;
  }
}

int main()
{
  int i,ans,Case=1;
  while(scanf("%s",str1)!=EOF)
  {
    nn=strlen(str1);
    n=2*nn+2;
    str[0]='$';
    for(i=0;i<=nn;i++)
    {
      str[2*i+1]='#';
      str[2*i+2]=str1[i];
    }
    Manacher(rad,str,n);
    ans=1;
    for(i=0;i<n;i++)
```

```
51        ans=rad[i]>ans?rad[i]:ans;
52      printf("%d\n",ans-1);
53    }
54  return 0;
55  }
```

1.4 ac 自动机

```
1  char str[2000010];
2  char c[1010][55];
3
4  namespace AC {
5  const int dict = 26;
6  const int root = 0;
7  const int maxn = 3000000;

47                  tree[nxt].fail = tree[f].son[i];
48                  q.push(nxt);
49              } else  tree[cur].son[i] = tree[f].son[i];
50      }
51  }
52  void search(char *s) {
53      int i, cur = 0;
54      for ( ; *s ; s++ ) {
55          if( (*s) >= 'A' && (*s) <= 'Z' ) {
56              cur = tree[cur].son[*s - 'A'];
57              for ( i = cur ; i ; i = tree[i].fail ) { //用于优化vis
58                  apr[tree[i].idx]++;
59              }
60          } else {
61              cur = 0;
62          }
63      }
64      for(int i = 1; i <= 1010; ++i) {
65          if(apr[i]) {
66              printf("%s: %d\n", c[i], apr[i]);
67          }
68      }
69  }
70  };
71
72  int main() {
73    //  freopen("input.txt", "r", stdin);
74      int n;
75
76      while(scanf("%d", &n) != EOF) {
77          AC::init();
78          for(int i = 1; i <= n ; ++i) {
79              scanf("%s", c[i]);
80              AC::ins(c[i], i);
81          }
82          AC::buildac();
83          getchar();
84          gets(str);
85          AC::search(str);
86      }
87
88      return 0;
89  }
```

1.5 后缀数组

da 函数的参数 m 代表字符串中字符的取值范围，是基数排序的一个参数，如果原序列都是字母可以直接取 128，如果原序列本身都是整数的话，则 m 可以取比最大的整数大 1 的值。
height[i]=LCP(i-1,i) LCP(i,j)=lcp(Suffix(SA[i]),Suffix(SA[j]))

就是从 sa[i] 开始的后缀与从 sa[j] 开始的后缀的最长公共前缀
LCP(i,j)=minheight[k] | i+1 k j 此时的 i，j 为 suffix 的对应值
例：abaca
rk 2 4 3 5 1 0
sa 5 4 0 2 1 3
height 0 0 1 1 0 0

```
const int maxn = 2010;
int wa[maxn],wb[maxn],wv[maxn],wss[maxn],sa[maxn];
bool cmp(int *r,int a,int b,int l)
{
  return r[a]==r[b]&&r[a+l]==r[b+l];
}
void da(int *r,int *sa,int n,int m)
{
  int i,j,p,*x=wa,*y=wb,*t;

  for(i=0;i<m;i++) wss[i]=0;
  for(i=0;i<n;i++) wss[x[i]=r[i]]++;
  for(i=1;i<m;i++) wss[i]+=wss[i-1];
  for(i=n-1;i>=0;i--) sa[--wss[x[i]]]=i;
  for(j=1,p=1;p<n;j*=2,m=p)
  {
    for(p=0,i=n-j;i<n;i++) y[p++]=i;
    for(i=0;i<n;i++) if(sa[i]>=j) y[p++]=sa[i]-j;
    for(i=0;i<n;i++) wv[i]=x[y[i]];
    for(i=0;i<m;i++) wss[i]=0;
    for(i=0;i<n;i++) wss[wv[i]]++;
    for(i=1;i<m;i++) wss[i]+=wss[i-1];
    for(i=n-1;i>=0;i--) sa[--wss[wv[i]]]=y[i];
    for(t=x,x=y,y=t,p=1,x[sa[0]]=0,i=1;i<n;i++)
      x[sa[i]]=cmp(y,sa[i-1],sa[i],j)?p-1:p++;
  }
}
int rk[maxn],height[maxn];
void calheight(int *r,int *sa,int n)

45    int n=strlen(ch);
46    fr(i,0,n) add( ch[i] - 'a');
47    int i;
48    caltimes(n);
49    return 0;
50  }
```

1.7 elfhash

如果最高的四位不为 0，则说明字符多余 7 个，现在正在存第 8 个字符，如果不处理，再加下一个字符时，第一个字符会被移出，因此要有如下处理。
该处理，如果对于字符串 (a-z 或者 A-Z) 就会仅仅影响 5-8 位，否则会影响 5-31 位，因为 C 语言使用的算数移位
因为 1-4 位刚刚存储了新加入到字符，所以不能右移 28
上面这行代码并不会对 X 有影响，本身 X 和 hash 的高 4 位相同，下面这行代码即对 28-31(高 4 位) 位清零。
返回一个符号位为 0 的数，即丢弃最高位，以免函数外产生影响。(我们可以考虑，如果只有字符，符号位不可能为负)
hash 左移 4 位，把当前字符 ASCII 存入 hash 低四位。

```
1  unsigned int ELFHash(char *str)
2  {
3    unsigned int hash = 0;
4    unsigned int x = 0;
5
6    while (*str)
7    {
8      hash = (hash << 4) + (*str++);
9      if ((x = hash & 0xF0000000L) != 0)
10     {
11       hash ^= (x >> 24);
12       hash &= ~x;
13     }
14   }
15   return (hash & 0x7FFFFFFF);
16 }
```

1.8 散列 hash

```
1  struct hash_map{
2    const static int P = 999887;
```

```
  int head[P], next[N],key[N];
  int sz;
  inline void init(){
    cl(head), sz = 0;
  }
  inline int find(uint val){
    int x = val % P;
    for (int i=head[x]; i; i=next[i])
      if (key[i] == val) return i;
    return 0;
  }
  inline int insert(uint val){
    ++sz; key[sz] = val;
    int x = val % P; next[sz] = head[x]; head[x] = sz;
    return sz;
  }
} hashed;
```

1.9 可获取任意段字符串的 hash

```
unsigned int S[N],P[N];
void init(char *str,int n){
  S[0] = 1,P[0] = 1;
  fr(i ,1, n+1) P[i] =P[i-1]*Z;  //是zbase
  fr(i , 0 ,n) S[i+1] = S[i]*Z+(str[i]-'a'+1);
}
int H(PLD x){  //这里获得一段的值hash  x.l r 收尾位置
  int l=x.l; int r=x.r;
  return S[r+1] - S[l] * P[r-l+1];
}
```

2 数学

2.1 素数

2.1.1 筛素数

```
bool flag[N+1];
int prime[N+1];
int totpri;
void getpri(){
  int n=N;
  int i,j;totpri=0;
  for(i=2;i<=n;++i) { /*筛选素数快速的方法*/
    if(!flag[i]) prime[totpri++]=i;
    for(j=0;j<totpri&&i*prime[j]<=n;++j)
    {
      flag[i*prime[j]]=1;
      if(i%prime[j]==0) break;
    }
  }
}
```

2.1.2 Miller-Rabbin

```
bool primeTest(ll n, ll b) {
    ll m = n - 1;
    ll counter = 0;
    while ((m & 1) == 0) {
        m >>= 1;
        counter ++;
    }
    ll ret = pow_mod(b, m, n);
    if (ret == 1 || ret == n - 1) {
        return true;
    }
    counter --;
    while (counter >= 0) {
        ret = add_mod(ret, ret, n);

}
```

2.14 字典序

2.14.1 排列

```
int perm2num(int n, int *p) {
    int i, j, ret = 0, k = 1;
    for (i = n - 2; i >= 0; k *= n - (i--))
        for (j = i + 1; j < n; j++)
            if (p[j] < p[i])
                ret += k;
    return ret;
}
void num2perm(int n, int *p, int t) {
    int i, j;
    for (i = n - 1; i >= 0; i--)
        p[i] = t % (n - i), t /= n - i;
    for (i = n - 1; i; i--)
        for (j = i - 1; j >= 0; j--)
            if (p[j] <= p[i])
                p[i]++;
}
```

2.14.2 组合

```
int comb(int n, int m) {
    int ret = 1, i;
    m = m < (n - m) ? m : (n - m);
    for (i = n - m + 1; i <= n; ret *= (i++));
    for (i = 1; i <= m; ret /= (i++));
    return m < 0 ? 0 : ret;
}
int comb2num(int n, int m, int *c) {
    int ret = comb(n, m), i;
    for (i = 0; i < m; i++)
        ret -= comb(n - c[i], m - i);
    return ret;
}
```

```
14 void num2comb(int n, int m, int* c, int t) {
15     int i, j = 1, k;
16     for (i = 0; i < m; c[i++] = j++)
17         for (; t > (k = comb(n - j, m - i - 1)); t -= k, j++);
18 }
```

2.15 置换 polya

求置换的循环节,polya 原理
perm[0..n-1] 为 0..n-1 的一个置换 (排列)
返回置换最小周期,num 返回循环节个数

```
1  #define MAXN 1000
2  int polya(int* perm, int n, int& num) {
3      int i, j, p, v[MAXN] = {0}, ret = 1;
4      for (num = i = 0; i < n; i++)
5          if (!v[i]) {
6              for (num++, j = 0, p = i; !v[p = perm[p]]; j++)
7                  v[p] = 1;
8              ret *= j / gcd(ret, j);
9          }
10     return ret;
11 }
```

3 数据结构

3.1 树状数组

注意 init 的时候要小一个 1

```
template<int MAXN=300000, typename T = int>
struct BIT {
  int n;
  T a[MAXN];

  void init(int n) {
    this->n = n;
    fill(a, a + n + 1, T());
  }
  void add(int i, T v) {
    for (int j = i; j <= n; j = (j | (j - 1)) + 1) {
      a[j] += v;
    }
  }
  //(0..i];
  T sum(int i) const {
    T ret = T();
    for (int j = i; j > 0; j = j & (j - 1)) {
      ret += a[j];
    }
    return ret;
  }
  T get(int i) const {
    return sum(i ) - sum(i-1);
  }
  void set(int i, T v) {
    add(i, v - get(i));
  }

  void add(int l , int r ,T v)  //need sum is ith val;get && set
     can't use;
  {
    add(l,v);add(r+1,-v);
  }
};
```

3.2 坐标离散

注意下标～

```
const int MaxN=100;
int axis[MaxN];
int r[MaxN];     //排序用到的数组;
int mp[MaxN]; //离散值到原始值的映射;
int M;       //离散值的最大值, [1, M];
```

```
bool cmp(int a, int b)  {return axis[a] < axis[b];}
void Lisan(int N)
{
  for(int i=0; i<N; i++)  r[i] = i;
  sort(r, r+N, cmp);
  mp[1] = axis[r[0]];
  axis[r[0]] = M = 1;
  for(int i=1; i<N; i++)
  {
    if(axis[r[i]] == mp[M]) axis[r[i]] = M;
    else  mp[++M] = axis[r[i]], axis[r[i]] = M;
  }
}
int main(){
  for (int i=0;i<5;i++) scanf("%d",&axis[i]);
  Lisan(5);
  return 0;
}
```

3.3 lca-rmq

```
using namespace std;
typedef long long ll;
const int N=10010;
int n;
